

TLC Data Project

A new project with the New York City Taxi & Limousine Commission (TLC).

Overview

The NYC TLC agency has partnered with Automatidata to develop a regression model that helps estimate taxi fares before the ride, based on data that TLC has gathered.

Objective

- Global-level project document
- Analysis of testing results between two important variables
- Determination the success of the model

Results

Automatidata analytics team is in the earliest stages of the TLC project. Database was created and organized and our current analyses derived the following :

- The data types are as follows: eight columns of type float, seven columns of type integer, and three columns of type object .
- The data contains a table of 18 columns (characteristic) and 22699 rows (ride record) with no null missing values.
- greater distance doesn't seem to reflect higher total amount. Thereore, there is no correlation between these two parameters . And there is no correlation between number of passengers and tip amount..
- Most of the users paid using their credit card, and the average tip amount for cash payments is zero.

Next Steps

- Our team will do further EDA on the data correlation between the two variables: total amount and trip distance.
- We believe that the given dataset is sufficient for the process and will contine our work to achieve the expected results.
